

#### Radiomics in oncology: present and future

Carolina de la Pinta Alonso

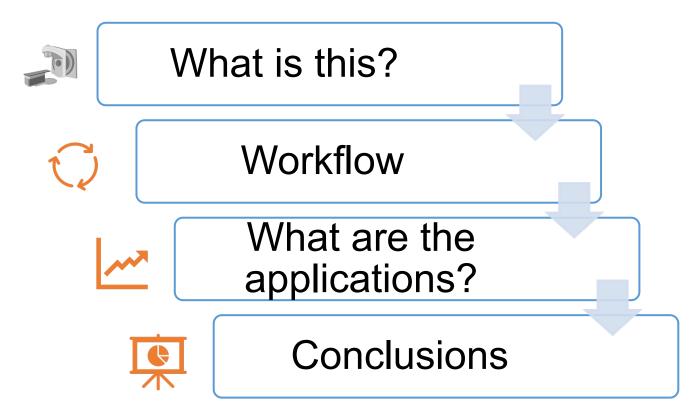

Physician in radiation oncology, MD, PhD

Hospital Universitario Ramón y Cajal, Madrid, Spain

#### **TABLE OF CONTENTS**

Radiomics makes it possible to analyze and extract data from medical

images, including quantitative and qualitative characteristics.

- CT, MRI and PET using computer software.
- More precise delimitation of tumor, the tumor microenvironment or alterations after treatment.

This requires:

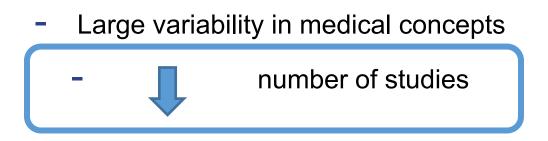

- 1. Image acquisition
- 2. Dataset creation
- 3. Export of DICOM studies
- 4. Identification of the volume of interest (VOI) using segmentation tools
- 5. Feature extraction and qualification
- 6. Study of the data
- 7. Construction of a predictive model
- 8. Validation of the created models

The use of convolutional neural networks (CNNs) in medical image analysis is growing, outperforming traditional machine learning (ML) algorithms on large datasets.

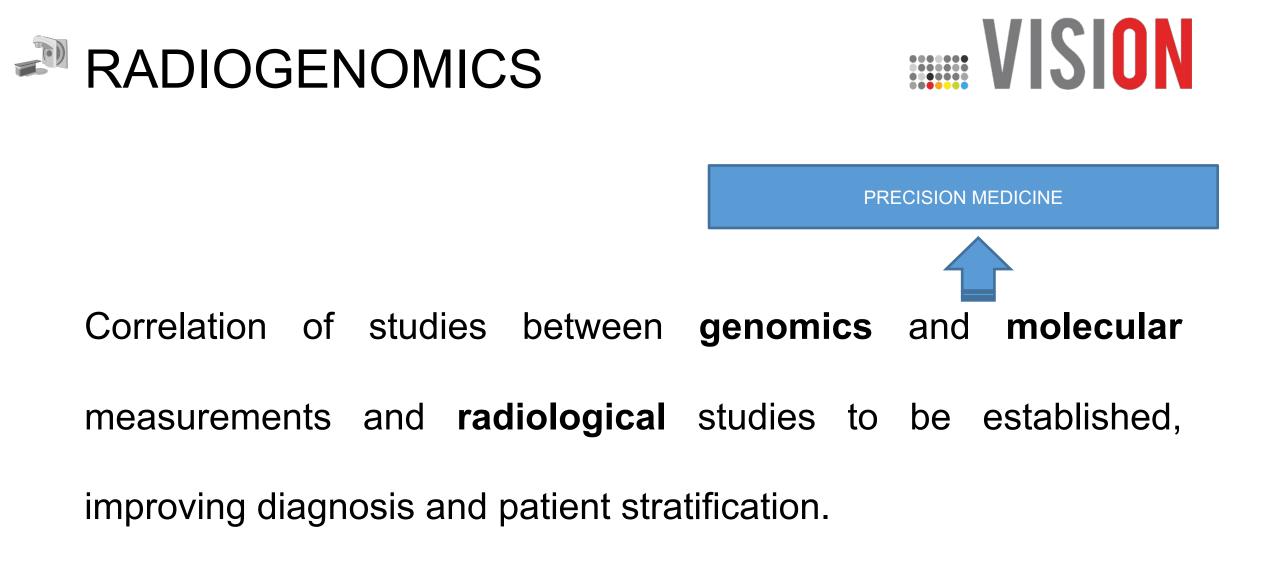

#### **Problems**

Pre-training studies is proposed with promising results for different image analysis tasks.

Ziegelmayer S, et al. J Clin Med 2020;9:4013. Barat M, et al. Jpn J Radiol 2021;39:514–523. Weisberg EM, et al. Diagn Interv Imaging 2020;101:111–115. Kaissis G, et al. Eur Radiol Exp 2019;3:41.

Terminology	Short Definition
Radiomics	Quantitative approach to medical imaging, enhancing existing data through mathematical analysis [68].
Genomics	Study of whole genomes, including elements from genetics. Genomics uses a combination of recombinant DNA, DNA sequencing methods, and bioinformatics to sequence, assemble, and analyze the structure and function of genomes [69–71].
Radiogenomics	Genomics information that can be explained or decoded by radiomics and to develop methodology to create more-efficient predictive models [72].

Table 1. Short definitions for specific medical terms.

DNA = deoxyribonucleic acid.

# 1. Image acquisition and reconstruction

• **Characteristics:** kV, mAs, slice size, breath control method,

configuration, contrast.

- Standardization of image data
  - Can help to establish predictive models.
  - Important in the final results of the analysis (homogeneous criterion)

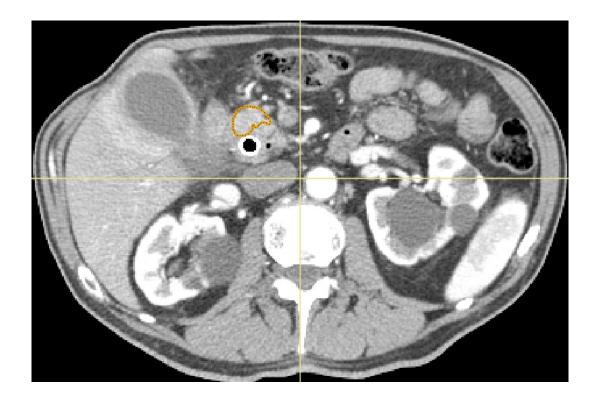

Radiomics based on non-contrast CT images has shown in some studies a higher efficiency compared to contrast CT images.

# Q 2. Segmentation of the area of interest (I)

• ROI (Region of interest) = segmentation.

# Q 2. Segmentation of the area of interest (II)

Types of segmentation: Manual, automatic, or semi-automatic.

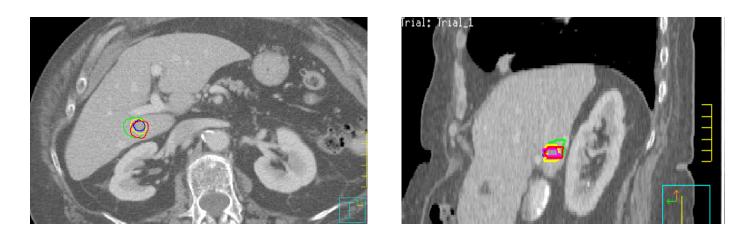

- Gold standard → manual segmentation by experts but is operator dependent
- Automatic segmentation: uses preselected parameters and is ideal for its accuracy, reproducibility, and consistency but manual intervention is necessary to validate the automatic segmentation.
- There is no universal method, the same algorithm can give variable results.
- The semiautomatic segmentation is able to combine two previous procedures being the **most recommended**.

# Q 2. Segmentation of the area of interest (III)

#### Is crucial, an error in this phase will modify the whole analisis.

Weisberg EM, et al. Diagn Interv Imaging 2020;101:111–115. Kaissis G, et al. Eur Radiol Exp 2019;3:41. Bartoli M, et al. Jpn J Radiol 2020;38:1111–1124

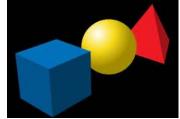

- 4 types of analysis:
- **1.** Morphological  $\rightarrow$  the most basic radiomics analysis
- 2. Statistical→ includes first-order (histogram) and highly-order features (texture)
- Regional→ intratumor heterogeneity and characteristics around the tumor
- **4.** Model-based  $\rightarrow$  is analyzed with a mathematical approach

• Morphological analysis includes:

#### Shape.

To evaluate physical characteristics and differentiates between malignant and benign lesions.

**Include**: diameter, volume, area under the curve (AUC), and wave.

Lesions are constructed in 3D images.

The most commonly used: maximum and minimum diameter, and volume.

Muhi A et al. J Magn Reson Imaging 2012;35:827–836. Zaheer A, et al. J Comput Assist Tomogr 2014;38:146–152. Cheng MF, et al. Sci Rep 2018;8:3651. Park S, et al. Diagn Interv Imaging 2020;101:555–564. Chu LC, etl al. AJR Am J Roentgenol 2019;213:349–357.

The volume is defined by counting the number of voxels in the tumor and multiplying by the volume of the voxel.

**Volume** is a **key parameter**, a short volume doubling time reflects high histological aggressiveness and suggests poor prognosis, volume is a tool for evaluating response to treatment.

Muhi A et al. J Magn Reson Imaging 2012;35:827–836. Zaheer A, et al. J Comput Assist Tomogr 2014;38:146–152. Cheng MF, et al. Sci Rep 2018;8:3651. Park S, et al. Diagn Interv Imaging 2020;101:555–564. Chu LC, etl al. AJR Am J Roentgenol 2019;213:349–357.

### O 3. Extraction and quantification of features (IV)

## 

- Is analyzed in histograms which are graphic representations of the intensity distribution in an image.
- Analysis **includes**:

Intensity

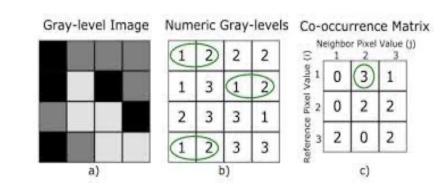

- Range, mean, median, standard deviation (SD), minimum, maximum, kurtosis, energy, entropy (describes the randomness of the surrounding intensities within a grayscale image), uniformity, variance, and skewness
- Can be used to predict the nature of the lesion and prognosis.
- Characteristics are dependent on the reconstruction and image acquisition parameters (cut size and voxel size).

#### **Texture**

- Describes the relationship between neighboring pixels and their distribution through the nodes.
- Determines the tumor's heterogeneity (differentiation between benign and malignant lesions).
- For texture extraction, the most used method includes second-order statistics and cooccurrence matrix characteristics constructed using number, distance, and angle of gray levels in the image.
- Includes: correlation, clustering, contrast, energy, and entropy.

#### > Wavelet

- Allows to decompose the image data into different frequency components and uses these data to extract characteristics related to the **texture** and **intensity** of the image.
- These are filters that transform an array of complex lines or radio waves.
- The most common is the **Coiflet wave transformation**.
- They are used in the diagnosis and evaluation of response to treatment.

- The relationship between the tumor and the surrounding healthy surface is another element of the tumor microenvironment.
- The discrete compaction is related to its circularity and this to the invasion around the tumor.
- The neighboring gray tone matrix is a parameter to differentiate gray tones, including busyness, complexity, and texture length.
- It is necessary to evaluate these data with statistical covariance.

*4. Construction of predictive models and prognosis in a non-invasive method*

- Relationships between radiomics parameters and clinical variables.
- This can be done from direct statistical analysis based on hypotheses on machine learning methods.

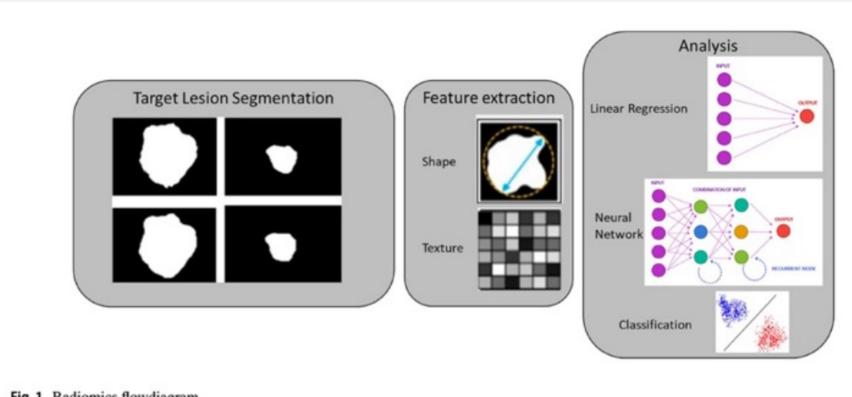

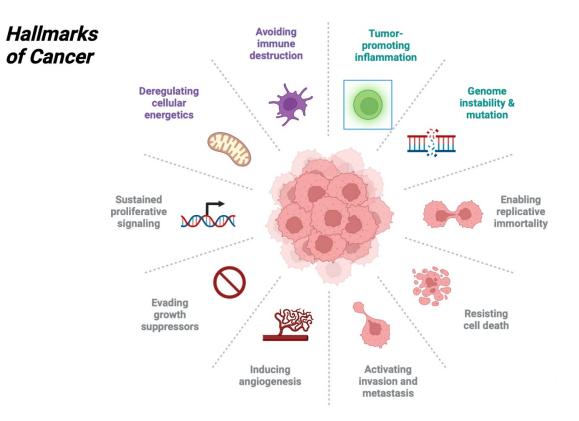

Fig. 1 Radiomics flowdiagram

Radiomics in medical imaging: pitfalls and challenges in clinical management Roberta Fusco et al. Japanese Journal of Radiology https://doi.org/10.1007/s11604-022-01271-4

### WHAT ARE THE APPLICATIONS?

#### *Differential diagnosis IN PANCREATIC LESIONS*

## **VISION**

#### Table 1

Radiomics studies in differentiation of pancreatic cystic lesions.

Studies	n	Туре	Model	Clinical	Segmentation	Features	Differentation between entities

de la Pinta C. Radiomics in pancreatic cancer for oncologist: Present and future. Hepatobiliary Pancreat Dis Int. 2022 Aug;21(4):356-361. doi: 10.1016/j.hbpd.2021.12.006. Epub 2021 Dec 16. PMID: 34961674.

#### Differential diagnosis IN neuro

fferential diagnosis IN uroendocrine tumors				
Studies	n	Image	Features	Results
Lin et al. [30]	PNET $(n = 21)$ Intra-pancreatic spleen $(n = 13)$	СТ	Texture, entropy, skewness, kurtosis and uniformity	Less heterogeneous enhancement in arterial and portal phase in PNET (69% vs. 35%, $P = 0.06$ ; 100% vs. 29%, $P = 0.04$ ). Entropy and uniformity ( $P < 0.01$ ). Uniformity with sensitivity of 85%-95% and specificity of 75%-83.3% to differentiate.
Choi et al. [31]	PNET $(n = 66)$ : grade $1(n = 45)$ ; grade $2/3$ $(n = 21)$	СТ	Texture	Predictors of grade 2/3 were a well-defined margin (OR = 7.273). Low sphericity (OR = 0.409) in 2D arterial analysis, high skewness (OR = 1.972), low sphericity (OR = 0.408) in 3D analysis, low kurtosis (OR = 0.436), low sphericity in 2D portal (OR = 0.420) and in 3D (OR = 0.503) ( $P < 0.05$ ), large surface area (OR = 2.007). Texture-based diagnosis was superior to CT findings (AUC = 0.774 vs. 0.683).
Canellas et al. [32]	Pre-surgery ( <i>n</i> = 101)	СТ	Texture	Size larger than 2 cm was predictive of higher grade (OR = 3.3; P = 0.014). Presence of vascular involvement (OR = 25.2; $P = 0.03$ ), pancreatic duct dilatation (OR = 6.0; $P = 0.002$ ), presence of lymphadenopathy (OR = 25.2; $P = 0.003$ ), entropy (OR = 3.7; $P = 0.008$ ) were predictive of more aggressive tumors. Differences were observed in progression free survival for grade 1 versus grade 2 tumors for PNETs with vascular involvement; and for tumors with entropy ( $P < 0.001$ ).
Li et al. [33]	n = 127: pancreas adenocarcinoma (n = 50) PNETs $(n = 77)$	СТ	Texture	Atypical PNETs had high mean, median, 5th, 10th and 25th percentiles ( $P = 0.006$ , 0.024, < 0.001, 0.001, 0.021, respectively) and low skewness ( $P = 0.017$ ). No differences in 75th and 90th percentiles, kurtosis, and

PNET: pancreatic neuroendocrine tumor; CT: computed tomography; OR: odds ratio; AUC: area under curve.

entropy between the two tumors.

CT: computed tomography; DFS: disease free survival; NSCLC: non-small cell lung cancer; CRT: chemoradiotherapy, OS: overall survival; RT: radiotherapy; PET: positron emission tomography; LC: local control; DMFS: distant metastases free survival; AC: adenocarcinoma; SBRT: stereotactic body radiotherapy; TKI: tirosin kinasa inhibitors; SUV: standardized uptake value; AUC-CSH: area under curve of the cumulative SUV-volume histogram; IVH: intensity volume histogram ; COV: coefficient of variation

de la Pinta C, Barrios-Campo N, Sevillano D. Radiomics in lung cancer for oncologists. J Clin Transl Res. 2020 Sep 2;6(4):127-134. PMID: 33521373; PMCID: PMC7837741.

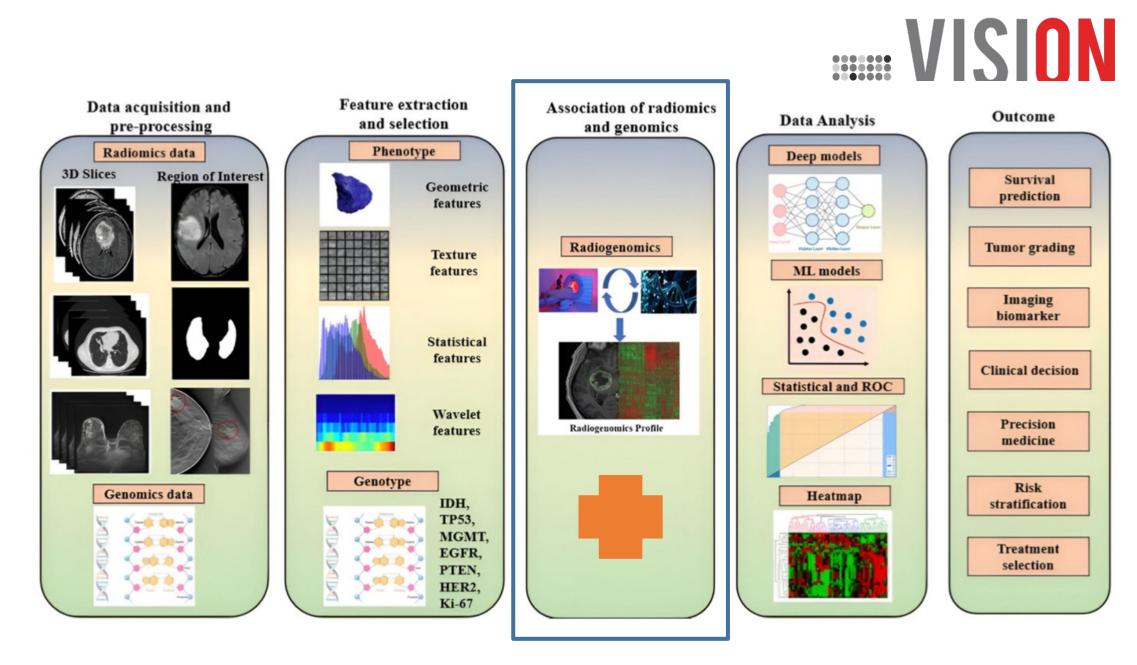

- The genetic study of tumors has allowed the development of targeted therapies, and the stratification of patients in terms of risk of relapse, prognosis, prediction of response and survival.
- The correlation of genetic alterations or tumor microenvironment and radiological findings allows the use of these imaging tests as a non-invasive tool for personalized medicine.

### RENAL CELL CARCINOMA

Table 1. Summary of 20 reviewed articles on radiogenomics in clear cell renal cell carcinoma. Nature of feature extraction is indicated by "Radiologist" if features are scored by one or more radiologists. Elsewise, software derived features are indicated by "Computational". Number of selected features indicated in parenthesis. TAT (total adipose tissue), VAT (visceral adipose tissue), AUC (area under the curve), OR (odds ratio), HR (hazard ratio), CSS (cancer specific survival), OS (overall survival), PFS (progression free survival).

Gopal N, et al. The Next Paradigm Shift in the Management of Clear Cell Renal Cancer: Radiogenomics-Definition, Current Advances, and Future Directions. Cancers (Basel). 2022 Feb 4;14(3):793.

## Assessment of response to treatment

- The correct assessment of response in the treatment is fundamental in defining the success or failure of treatment interventions.
- Prediction of early response would improve treatment selection in these patients.
  - Radiomics and radiogenomics could be very useful.

# Technical problems, limitations and challenges (I)

- CT acquisition
- Reconstruction
- Kernels
- Tube currents
- Slice size
- Voxel size
- Grey level
- Delay of contrast enhancement

# Technical problems, limitations and challenges (II)

- Standardization of protocols is therefore important in clinical applications
  - Also many of the comparisons between diagnostic entities using radiomics are subjective and not clinically applicable.

- Radiomics is a promising non-invasive tool for the diagnosis and clinical management of tumors and the patients.
- The usefulness of radiomics has been studied in the differential diagnosis of benign, premalignant and malignant lesions.
- In addition, it can help in the more precise definition of lesions for chemotherpay and radiotherapy and assessment of response.
- Radiomics provides a more adequate and reproducible measurement of the tumor than other methods.
- In addition, the combination of radiomics and genomics has a promising future to biomarkers.
- However, image acquisition protocols and radiomic analysis systems need to be standardized and validation cohorts are needed.
- Further studies are needed to consolidate the available data.

#### THANK YOU
